**Supplementary figure S3.** Lack of a correlation between sensitivity of BC cells to AsiDNA and their proliferation rate. Survival (ordinate) was monitored by trypan blue staining and manual counting (10 days after treatment). Survival is expressed as the percentage of living cells relative to non-treated cells (NT). The doubling time (abscissa) was calculated by counting the cells during the 10 days of exponential growth. The correlation analysis between survival in the presence of AsiDNA and doubling time was performed using GraphPadPrism5 software and indicates that there is no significant correlation.
